

# Drag project: part 2

**Contributions from**  
*SPARC, QBOi, ISSI*

# Interesting drag/momentum Activities

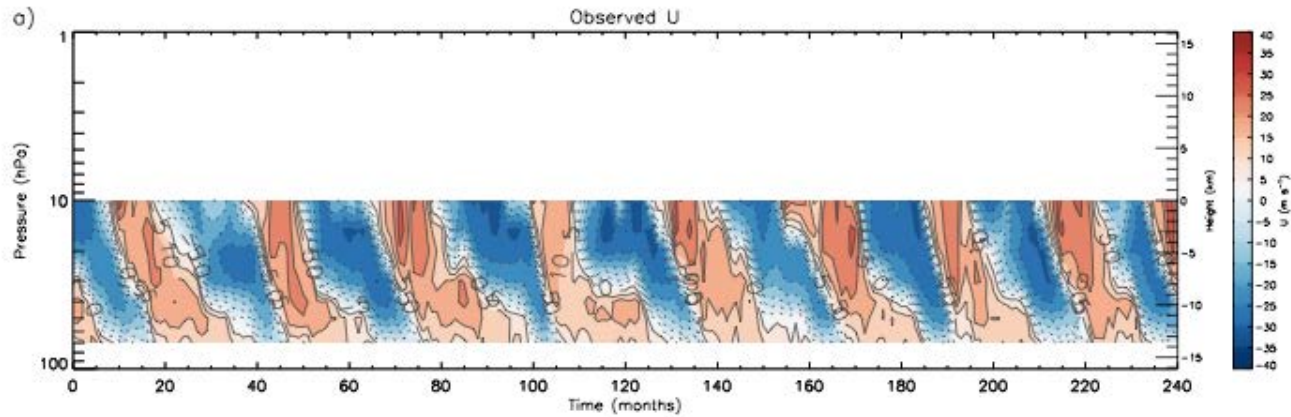

- SPARC GW activity (Kaoru Sato)
  - Surface drag, TEM diagnostic MIP in CMIP6
  - Surface drag fields added to HighResMIP
- ISSI momentum budget intercomparison (Joan Alexander, Naftali Cohen)
  - High-latitude focused study
- QBOi (Scott Osprey, Lesley Gray)
  - Kick-off meeting Victoria BC March 16-18 2015
  - Initial focus on QBO dynamics, but later on impacts as well

## QBO*i*

- QBO could provide a source of predictability
  - 26 month period, direct tropical as well as extratropical impacts.
- Many models now have a QBO
  - Generally too regular, don't penetrate deep enough, too confined in latitude
  - In all but 1 model, parameterized GW provide more momentum forcing than resolved waves
  - Vertical resolution important, but no agreement across models
- Glaring lack of observations to constrain wave momentum fluxes in the tropics

39, 2 / REVIEWS OF GEOPHYSICS

W-E QBO Composite of 1964-96 1000-hPa Z

**Figure 31.** Difference in 1000-hPa geopotential height composites (meters) between westerly and easterly QBO composites. December–February monthly-mean National Centers for Environmental Prediction data for 1964–1996 were used.

From *Baldwin et al. 2001*

# QBOi

- Initial experimental protocols
  - ~30 year AMIP simulation+corresponding simulation with climatological SSTs
  - 20 or so 6-12 month seasonal forecast runs with same models initialized with observations
  - Nudging runs – exact nature TBD – tropics only?, zonal-mean only?
- Output/diagnostics
  - A number of detailed QBO characterizations
  - Zonal mean TEM momentum budgets (***with residuals***) In all but
  - High frequency outputs (hourly) to calculate resolved wave characteristics

Observations to constrain wave momentum flux **Albert Hertzog LMD ... McMurdo Antarctica 2005(VORCORE), 2010 (CONCORDIASI)**

STRATEOLE / VORCORE

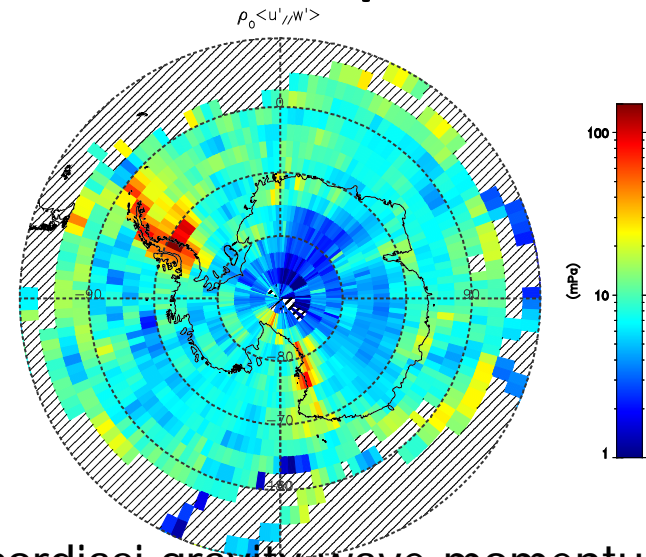

# Observations to constrain wave momentum flux *Albert Hertzog LMD ... McMurdo Antarctica 2005(VORCORE), 2010 (CONCORDIASI)*

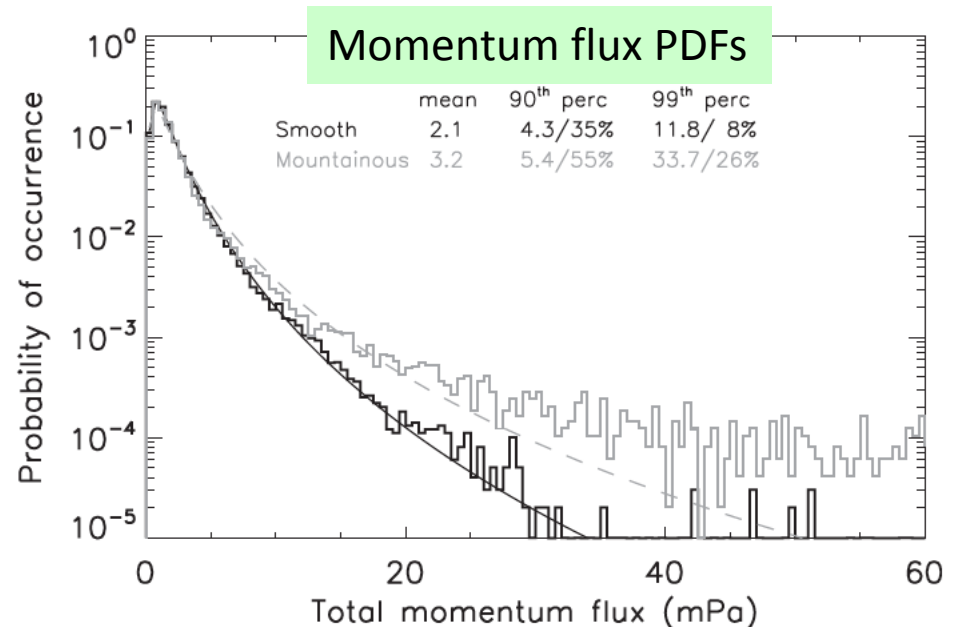

Concordiasi

19 flights, Sept-Jan 2010

Remain between 18 and 20km altitude**

Concordiasi gravity-wave momentum flux

## A long-duration balloon campaign to study the equatorial UTLS

Albert Hertzog

LMD, Palaiseau, France

albert.hertzog@lmd.polytechnique.fr

Riwal Plougonven

LMD, Palaiseau, France

plougon@lmd.ens.fr

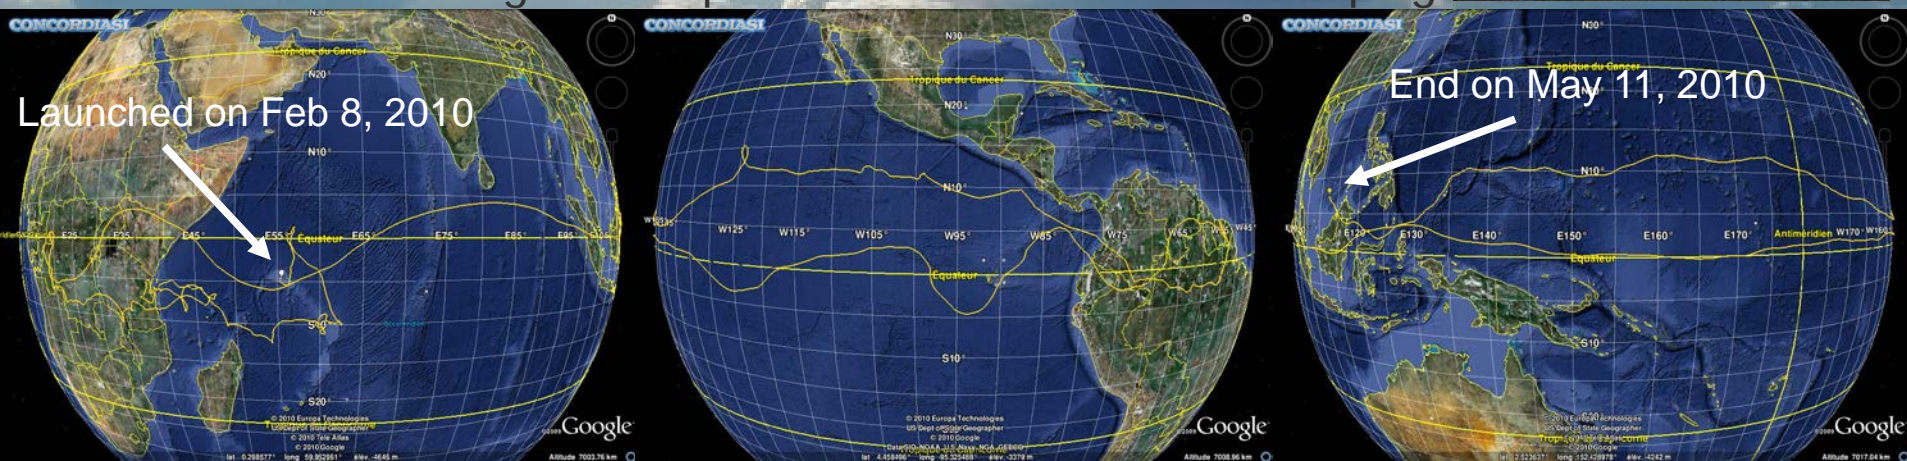

Philippe Cocquerez

CNES, Toulouse, France

philippe.cocquerez@cnes.fr

Flight example: 2010 Pre-Concordiasi campaign

Flight duration: 92 days

2 separate long-duration balloon campaigns

- 2018 and 2019 (to sample both phases of the QBO)
- About 20 flights per campaign

Scientific objectives

- Dynamics of the equatorial middle atmosphere: driving of the QBO (role of planetary/gravity waves), wave generation by deep convection, gravity-wave parameterization
- Transport and dehydration in the TTL: occurrence of penetrating convection, cirrus, supersaturation, cloud/dynamics interaction (long-duration balloons are quasi-Lagrangian tracers)
- Operational meteorology: accuracy of analyzed winds in the tropics, assimilation of balloon-borne observations
- Satellite validation (ADM/Aeolus, IASI on Metop)

**WGNE Action Item:**

**Letter of support for STRATEOLE2**

**“would be very helpful”**

**Decision point at the end of the year**

PROJECT LOON

WHAT IS LOON?

HOW LOON WORKS

WHERE LOON IS GOING

BALLOON-POWERED INTERNET FOR EVERYONE

# Extensions to parameterized orographic drag in CAM

- Scheme
- Evaluation in forecast mode and climate mode
- Future studies using DAS

# Blocking, low-level turning

(follows Scinocca&McFarlane 2000)

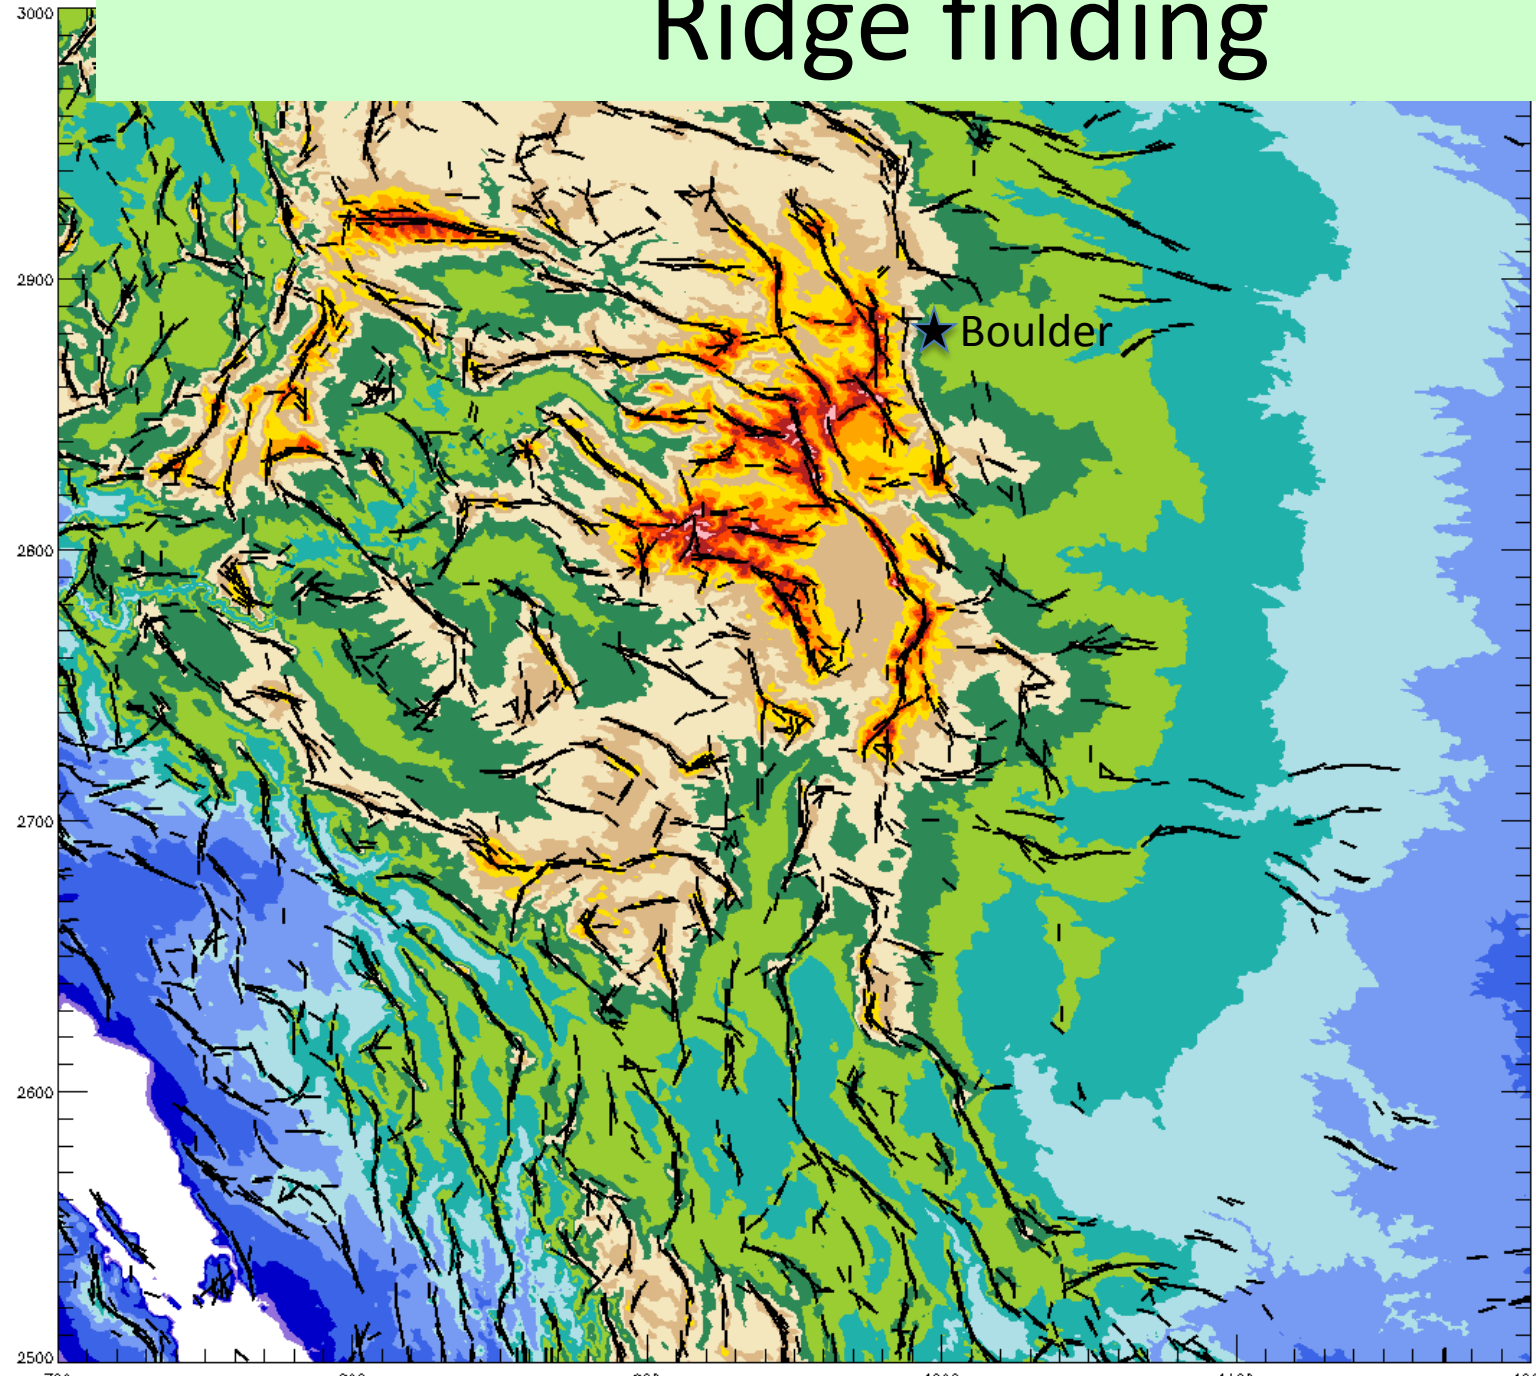

i – vertically propagating waves  $\partial_z \tau$  via saturation

ii - downslope wind layer  $\partial_z \tau \sim \partial_z \tau|_{sat} (1 + \gamma)$

iii – low-level flow turning  $\partial_z \tau \sim U^2$

# Ridge finding

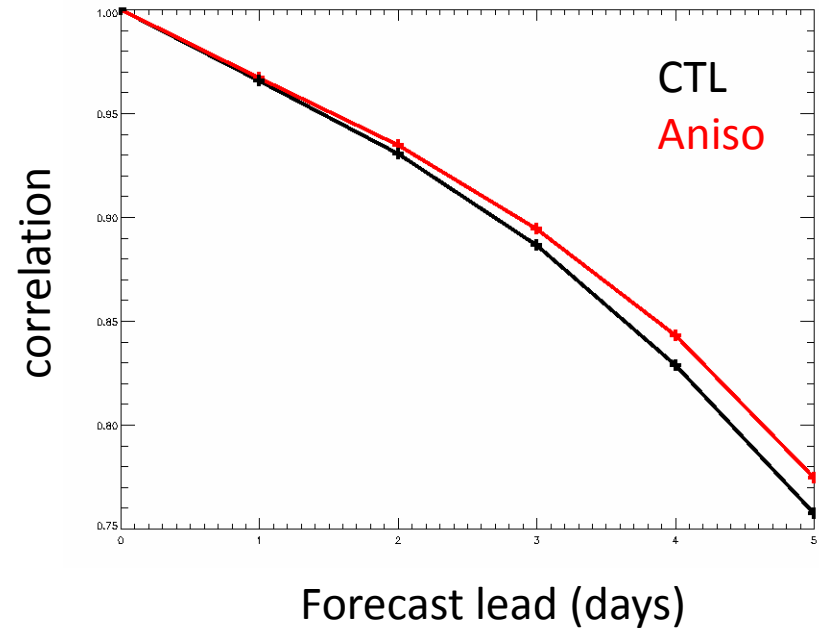

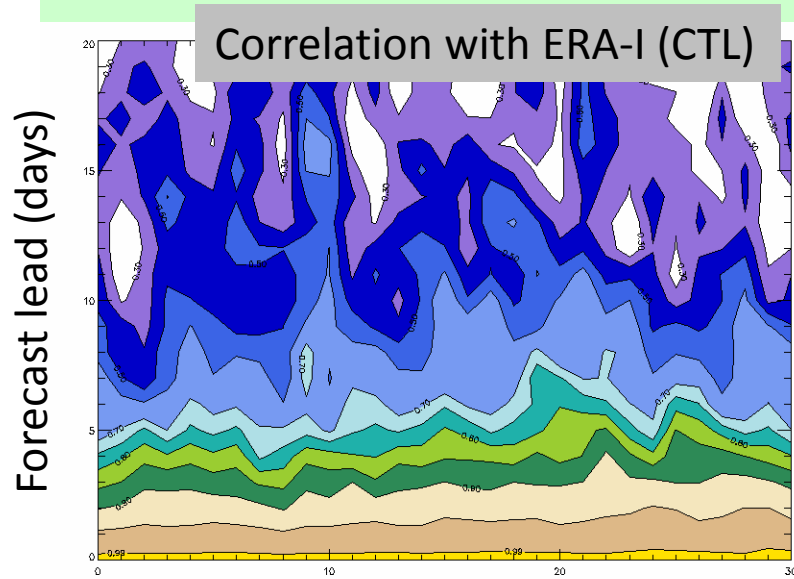

$L_s \sim 80\text{km}$

# CAPT forecasts 1/2003

- Forecasts initialized from ERA-I reanalyses
- Once per day 00Z (1/1-1/31) run for 20 days
- Validation against ERA-I (*could be a problem*)

# Forecasts of U at 700 hPa 1/2003

# Mean errors in 0.7-0.95 $\sigma$ -lev $U$ at Day 3

# Future work

Use full data assimilation system, e.g. DART, to examine scheme's impact on corrections/innovations ...

*smaller=better*

Extend this approach to evaluation of other schemes in CAM/CESM

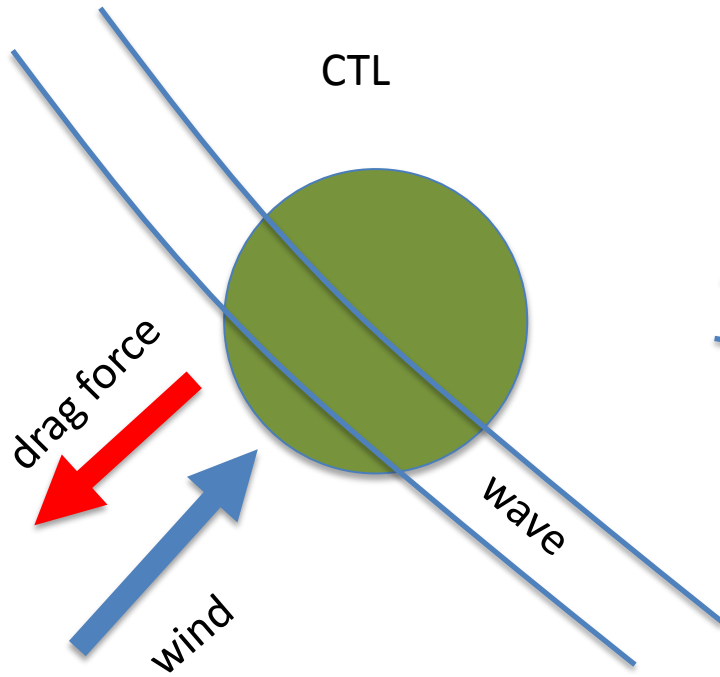

Thank You

Extra Slides

# Anisotropy

# Ridge finding

- Smooth (Bandpass) topography (scale  $\sim L_s$ )
- Calculate variances of mean cross-sectional profiles at 16 different orientations on  $L_a \times L_a$  domains
- Maximum 1D vs 2D variance determines “ridge” angle

- **Outputs**
  - Orientation
  - Ridge height (different from std. dev. of topo)
  - “quality” ratio of 1D/2D variance
  - Width

# Further innovations/complications

Multiple ridges possible in any AGCM gridbox depending on remapping from topo grid

2 families of ridges:

- Meso  $\beta$  800km-80km
- Meso  $\gamma$  80km-3km

Trapped lee wave parameterization.  
Uses width estimate to calculate

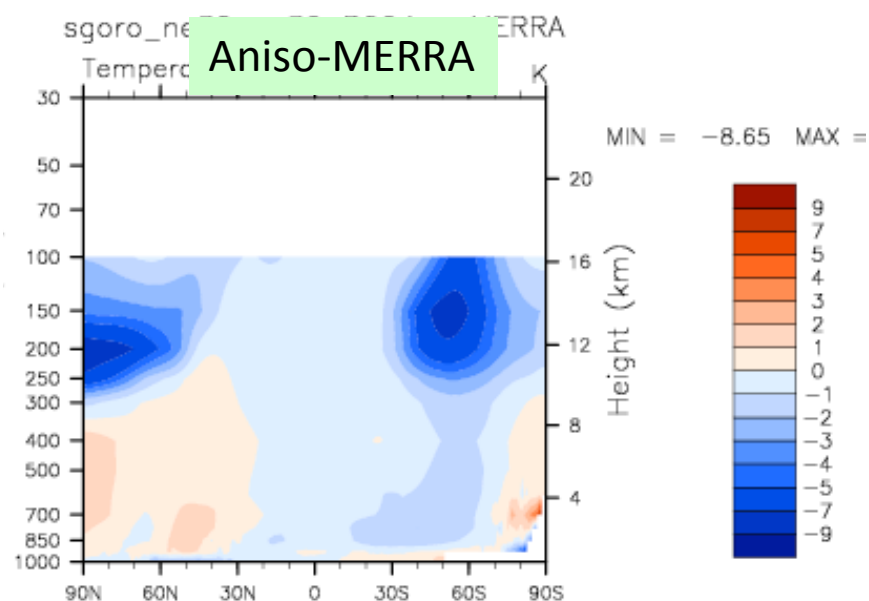

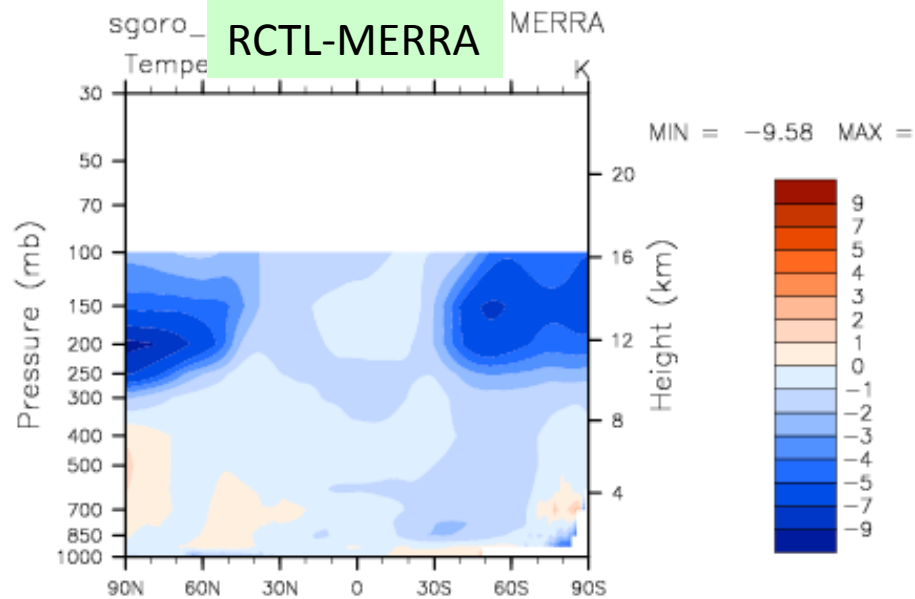

$$m^2 = \frac{N^2}{U^2} - k^2$$

# AMIP runs 1/1979-1/1990

- ne30
- 3 runs
  - **RCTL** - “rough” control. Rougher topo ( $L < 400\text{km}$ ) w/ old isotropic OGW scheme
  - **CTL** - control. Smoother topo ( $L < 800\text{km}$ ) w/ isotropic
  - **Aniso** – new anisotropic scheme w/ blocking, lee-waves etc..
- All still use TMS
- All use *low* value for divergence damping

# JJA Zonal mean temperatures

# New orographic drag scheme

- Anisotropy
- Low-level processes (blocking)
- Lee-wave trapping
- Multiple ridges and scales

**EXTRA SLIDES**

## Smooth topo (smoothing scale~800km)

1980-81 DJF mean  $\omega$  fields  
ne30~100km

### *CAM-SE is noisy*

2 approaches to mitigate this

- smoother topo
- increased divergence damping

## "Rough" topo (smoothing scale~400km)

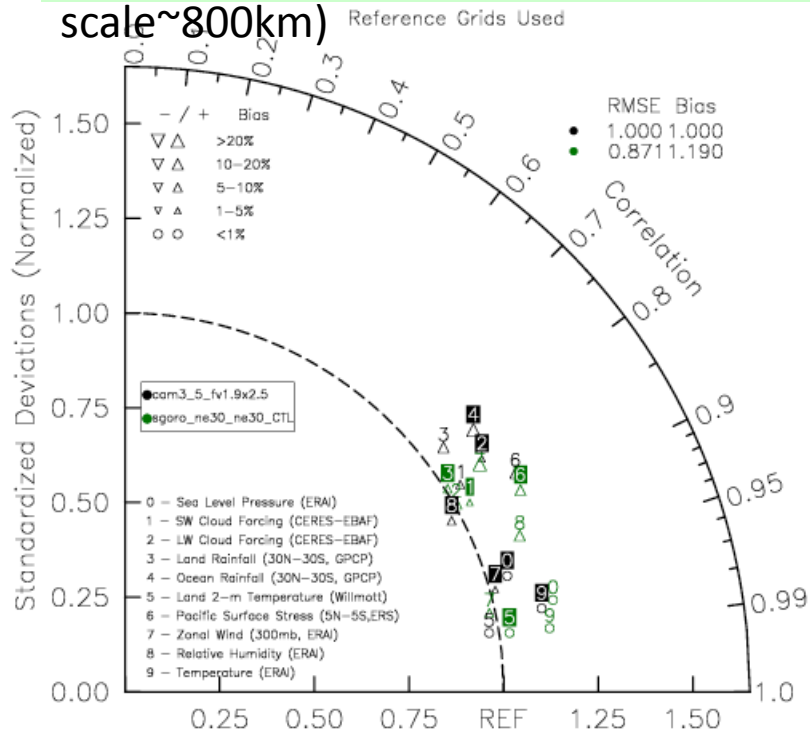

# Energy spectra

increased divergence  
damping impacts spectra

## Smooth top (smoothing scale~800km)

## "Rough" top (smoothing scale~400km)

Climate somewhat better overall with rougher topography
